TreasureMap

You need to implement the agents (*explorer.py* and *knowledgeable.py*) that enable the communication of the diagram, the **key_treasure** ontology is also represented.

The goal:

The **explorer agent** will explore a map with keys and treasures.

That world is implemented in the file `Simulator.py`, where the **explorer agent** is represented as **AA**. It already includes keys and treasures (the same ones as in the knowledge base (KB)).

The **explorer agent** will find treasures and keys. When it finds a key, the **explorer agent** must ask the **knowledge agent** which treasure that key opens and save that information.

The simulator will run until the explorer opens all the treasures.

To open a treasure, the **explorer agent** must have already found the correspondent key.

Some tips to start:

In your `explorer.py` add the following import: `from Simulator import *`
(you need to have the `Simulator.py` in the same directory)

In the main of your **explorer agent**, copy all the code in the main of the `Simulator.py`.

There, you need to modify the code between the comments to ask the **knowledgeable agent** which treasure the key found opens, and add that information with code like this: `key.treasure(treasure_name)`

Deliverables: You must upload the `explorer.py` and the `knowledge.py` in a ZIP file, named using your student numbers and names (12345_nomeapelido_54321_nomeapelido.zip), submit the ZIP file to the moodle.

Good luck :)
